

Programming Fundamentals

Function in C++

BS (SE) Fall-2025

Tasks

- Write a function `isEven(int n)` that returns true if `n` is even, otherwise false.
- Write a function `power(int base, int exponent)` that returns the result of $\text{base}^{\text{exponent}}$.
- Write a function `reverseNumber(int n)` that returns the reverse of a number.
- Create a function `countVowels(string s)` that counts the number of vowels in a string.

Agenda

- Function overview
- Modular programming
- Defining and calling functions
- Function prototype (declaration)

Function overview

- Function is a set of instruction that are designed to perform a specific task
 - Function is a complete and independent program
 - Divide a large program into smaller units
 - User defined and built-in functions
- Modular programming:
 - breaking a program up into smaller, manageable functions or modules
- Some advantages of functions
 - Functions makes a program clear and understandable
 - Finding errors will be easily (easy to debug)
 - Avoids code repetition and saves development time (code reusability)
 - Makes a program modification easy without changing the structure of a program (easy code maintenance)
 - Improves maintainability of programs
 - Simplifies the process of writing programs

Example

This program has one long, complex function containing all of the statements necessary to solve a problem.

[illegible]

In this program the problem has been divided into smaller problems, each of which is handled by a separate function.

```
int main()
{
    statement;
    statement;
    statement;
}
```

main function

```
void function2()
{
    statement;
    statement;
    statement;
}
```

function 2

```
void function3()
{
    statement;
    statement;
    statement;
}
```

function 3

```
void function4()
{
    statement;
    statement;
    statement;
}
```

function 4

User define functions

- Functions created by user as part of the program
- These functions are used for a specific use/purpose
- User defined function has three parts
 - Function declaration
 - Function definition
 - Function calling

Defining and Calling Functions

- Function call: statement causes a function to execute
- Function definition: statements that make up a function

Function Definition

- Definition includes: (Declarator and Body of Function)
 - return type: data type of the value that function returns to the part of the program that called it
 - name: name of the function. Function names follow same rules as variables
 - parameter list: variables containing values passed to the function
 - body: statements that perform the function's task, enclosed in { }

Example program

```
#include<iostream>
using namespace std;
int sum(int, int);
int main()
{
    int s;
    s = sum(5, 10);
    cout << "The sum is = " << s;
    return 0;
}

int sum(int a, int b)
{
    int sum = 0;
    sum = a + b;
    return sum;
}
```

Output:
The sum is = 15

Function Definition

```
Return type      Parameter list (This one is empty)
  |              |
  v              v
int main ()
{
    cout << "Hello World\n";
    return 0;
}
```

The diagram illustrates the structure of a C++ function definition. It shows the code `int main () { cout << "Hello World\n"; return 0; }` with four arrows pointing to its components: 'Return type' points to `int`, 'Function name' points to `main`, 'Parameter list (This one is empty)' points to `()`, and 'Function body' points to the code inside the curly braces.

Note: The line that reads `int main ()` is the *function header*.

Function Return Type

- If a function returns a value, the type of the value must be indicated:

```
int main()
```

- If a function does not return a value, its return type is `void`:

```
void printHeading()  
{  
    cout << "Monthly Sales\n";  
}
```

Calling a Function

- To call a function, use the function name followed by `()` and `;`
`printHeading();`
- When called, program executes the body of the called function
- After the function terminates, execution resumes in the calling function at point of call.

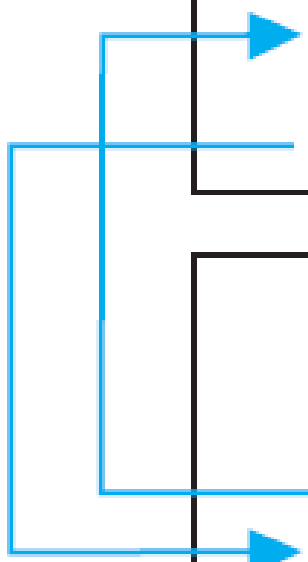

Example Program

```
1 // This program has two functions: main and displayMessage
2 #include <iostream>
3 using namespace std;
4
5 //*****
6 // Definition of function displayMessage *
7 // This function displays a greeting. *
8 //*****
9
10 void displayMessage()
11 {
12     cout << "Hello from the function displayMessage.\n";
13 }
14
15 //*****
16 // Function main *
17 //*****
18
19 int main()
20 {
21     cout << "Hello from main.\n";
22     displayMessage();
23     cout << "Back in function main again.\n";
24     return 0;
25 }
```

Program Output

```
Hello from main.
Hello from the function displayMessage.
Back in function main again.
```

Flow of Control in Program 6-1

```
void displayMessage()  
{  
    cout << "Hello from the function displayMessage.\n";  
}
```

The diagram shows a blue line starting from the left, branching into two arrows. One arrow points to the opening curly brace of the `displayMessage()` function, and the other points to the `displayMessage();` call inside the `main()` function.

```
int main()  
{  
    cout << "Hello from main.\n"  
    displayMessage();  
    cout << "Back in function main again.\n";  
    return 0;  
}
```

Calling Functions

- `main` can call any number of functions
- Functions can call other functions
- Compiler must know the following about a function before it is called:
 - name
 - return type
 - number of parameters
 - data type of each parameter

Function Prototypes

- Ways to notify the compiler about a function before a call to the function:
 - Place function definition before calling function's definition
 - Use a function prototype (function declaration) – like the function definition without the body
 - Header: `void printHeading()`
 - Prototype: `void printHeading();`

Example program

```
1  // This program has three functions: main, First, and Second.
2  #include <iostream>
3  using namespace std;
4
5  // Function Prototypes
6  void first();
7  void second();
8
9  int main()
10 {
11     cout << "I am starting in function main.\n";
12     first();    // Call function first
13     second();   // Call function second
14     cout << "Back in function main again.\n";
15     return 0;
16 }
17
```

(Program Continues)

Example program cont...

```
18  /*******
19  // Definition of function first.      *
20  // This function displays a message.  *
21  /*******
22
23  void first()
24  {
25      cout << "I am now inside the function first.\n";
26  }
27
28  /*******
29  // Definition of function second.     *
30  // This function displays a message.  *
31  /*******
32
33  void second()
34  {
35      cout << "I am now inside the function second.\n";
36  }
```

Prototype Notes

- Place prototypes near top of program
- Program must include either prototype or full function definition before any call to the function – compiler error otherwise
- When using prototypes, can place function definitions in any order in source file

Sending Data into a Function

- Can pass values into a function at time of call:

```
c = pow(a, b) ;
```

- Values passed to function are arguments
- Variables in a function that hold the values passed as arguments are parameters

A Function with a Parameter Variable

```
void displayValue(int num)
{
    cout << "The value is " << num << endl;
}
```

The integer variable `num` is a parameter.
It accepts any integer value passed to the function.

Example program

```
1  // This program demonstrates a function with a parameter.
2  #include <iostream>
3  using namespace std;
4
5  // Function Prototype
6  void displayValue(int);
7
8  int main()
9  {
10     cout << "I am passing 5 to displayValue.\n";
11     displayValue(5); // Call displayValue with argument 5
12     cout << "Now I am back in main.\n";
13     return 0;
14 }
15
```

(Program Continues)

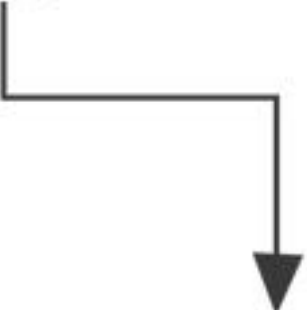

Example program cont...

```
16  /*******
17  // Definition of function displayValue.          *
18  // It uses an integer parameter whose value is displayed. *
19  /*******
20
21  void displayValue(int num)
22  {
23      cout << "The value is " << num << endl;
24  }
```

Program Output

```
I am passing 5 to displayValue.
The value is 5
Now I am back in main.
```

```
displayValue(5);  
  
void displayValue(int num)  
{  
    cout << "The value is " << num << endl;  
}
```

A diagram consisting of a vertical line from the closing parenthesis of 'displayValue(5);', followed by a horizontal line to the right, and then a vertical line ending in a downward-pointing arrowhead that points to the opening curly brace of the function definition 'void displayValue(int num) {'.

```
graph TD; A[displayValue(5);] --> B[void displayValue(int num) {  
    cout << "The value is " << num << endl;  
}]
```

The function call in line 11 passes the value 5 as an argument to the function.

Other Parameter Terminology

- A parameter can also be called a formal parameter or a formal argument
- An argument can also be called an actual parameter or an actual argument

Parameters, Prototypes, and Function Headers

- For each function argument,
 - the prototype must include the data type of each parameter inside its parentheses
 - the header must include a declaration for each parameter in its ()

```
void evenOrOdd(int);    //prototype  
void evenOrOdd(int num) //header  
evenOrOdd(val);        //call
```

Function Call Notes

- Value of argument is copied into parameter when the function is called
- A parameter's scope is the function which uses it
- Function can have multiple parameters
- There must be a data type listed in the prototype () and an argument declaration in the function header () for each parameter
- Arguments will be promoted/demoted as necessary to match parameters

Thank You All
